NEET Biology Anatomy of flowering plants

Definition of tissue

- A group of cells having a common origin and usually performing common function are called tissues.
- Plant tissues divided as:
- Meristematic Tissue: a). Apical Meristem
 - b). Intercalary Meristem
 - c). Lateral Meristem

Permanent Tissue:

- 1. Simple Permanent Tissue:
- a). Parenchyma
- b). Collenchyma
- c). Sclenenthyma
- 2. Complex Permanent Tissue:
- a). Xylem
- b). Phloem
- Parenchyma is a Simple permanent living tissue
- **Collenchyma** Consists of cells which are much thickened at corner due to cellulose, hemicelluloses and pectin. They provide mechanical support to the growing parts of the plant like young stem.
- Sclerenehymas are supportive tissue having highly thick walled cells with little or no protoplasm due to deposition of cellulose or lignin. They are of two types fibres and sclereids.

 Complex Tissues - Xylem and phloem constitute the complex tissues in plants and work together as a unit.

Xylem:

- It conducts water or sap.
- Xylem is made up of vessels, tracheid, xylem fibre and xylem parenchyma.

Phloem:

Phloem conducts organic food.

Phloem is made up of sieve tube, companion cells, pholem parenchyma and phloem fibres.

- Primary xylem is of two types Protoxylem and mataxylem.
- In gymnosperms, albuminous cells and sieve cells, they lack sieve tube and companion cells.

Epidermal Tissue System

- It forms the outermost covering of whole plant body, which consists of epidermal cells, stomata, epidermal appendages (trichomes and hairs).
- In dicots, stomata are bean- shaped having two guard cells closing the stomatal pore. In monocots, stoma is dumbbell-shaped. Guard cells contain chloroplasts that help in opening and closing of stomata.
- Trichomes are present on stems, which are multicellular, branched or unbranched preventing water loss due to transpiration.

The ground Tissue System

- All the tissue between epidermis and vascular bundle forms, the ground tissues.
- Leaves the mesophyll, chloroplast containing cell forms the ground tissues.

The Vascular Tissue System

- The vascular system consists of complex tissue, xylem and phloem that together form vascular bundles.
- Open vascular bundle (cambium between xylem and phloem) found in dicot stem.
- Closed vascular bundle (cambium absent between xylem and phloem) found in monocot stem.
- When xylem and phloem within a vascular bundle are arranged in alternate manner on different radii, the arrangement are called radial as in roots.
- When xylem and phloem are situated at the same radius of vascular bundle. It is called conjoint as in stem and leaves.

Dicotyledonous Root

- The outermost layer of dicot root is epidermis containing unicellular root hairs.
- The innermost layer of cortex is called endodermis having waxy material suberin as casparian strips.
- Pericycle is present below endodermis.
- Two to four xylem and phloem patches are present.

Monocotyledonous Roots

• Anatomically monocots roots epidermis cortex, endodermis, pith are similar to dicots except having more than 6 vascular bundles with larger pith.

NEET Biology Anatomy of flowering plants

Olcotyleclonous Stem

- Epidermis Is the outermost layer of dicot stems having thin layer of cuticle, may contain trichomes and hairs.
- Cortex is divided into three sub layers- outer hypodermis (collenchymatous), middle cortical layer (parenchymatous) and inner endodermis, which is rich in stanch grains so, also known as starch sheath.
- Vascular bundles are conjoint, open, endarch with protoxylem, Pith is the parenchymatous with intercellular spaces.

Monocotyledonous Stem

• They have sclerenchymatous hypodermis, large number of scattered vascular bundles surrounded by sclerenchymatous bundle sheath. Vascular bundles closed and conjoint. Phloem parenchyma is absent

Dicotyledonous Leaf (Dorsi-ventral)

- Epidermis covers both upper(adaxial) and lower (abaxial) surface. Abaxial surface have more stomata.
- Mesophyll bears chlorophyll to carryout photosynthesis, are made up of parenchyma. Spongy parenchyma are spherical and loosely arranged but palisade parenchyma are elongated.
- Vascular system includes vascular bundles, which are seen as seen as veins and midribs.

Monocotyledonous leaf (Isobilateral)

- Stomata are present on both surfaces of epidermis and mesophyll cells are not differentiated as spongy and palisade cells.
- In grasses, some adaxial epidermal cell with veins modify into large, empty, colourless cells called bulliform cells.

NEET Biology Anatomy of flowering plants

Secondary Growth

- It is the growth in girth (thickness) due to the formation of secondary tissues by lateral meristems (vesicular cambium and cork cambium).
- In dicot Stem, cambium present between xylem and phloem is called intrafascicular cambium. The cells of medullary rays become meristematic to form interfascicular cambium, which together form the complete ring of cambium.

- Cork cambium or phellogen is formed in the outer cortex of Stem.
- Cork is impervious to water due to deposition of suberin in cell wall. Phellogen, phellem and phelloderm are collectively called periderm.
- Secondary growth also occurs in stem and root of Gymnosperms but not in monocotyledons.
